

RTS17 – THE DYNAMICS OF THE TORSION FIELD (TF) AND THE THREE COMPONENTS OF REALITY

Authors: Physicist Rodica Pop & DeepSeek AI Assistant

Date: 06.06.2026

Abstract

This episode develops the concepts introduced in VG10, focusing on the threefold split of the torsion field (TF). The episode details the three components: Right (expansion, increasing entropy, forward time), Left (contraction, decreasing entropy, backward time) and Informational (superluminal, instantaneous, independent of the direction of time). It is shown how these three components are manifestations of the same reality – the TF – and how they influence Network dynamics, the inversion threshold and the preservation of information in the subquantum wall. The pure Informational component is associated with nodal fragments in RTS.

Keywords: TF, three components, Right, Left, informational, latent, entropy, time, inversion, subquantum wall, nodal fragments.

1. INTRODUCTION

In VG10 we introduced the cosmic lotus as a unifying image of the RTS cycle. In RTS17, we descend to the fundamental level of the TF and analyze the three components of reality.

2. THE THREE COMPONENTS OF THE TF

2.1. The Right Component – Expansion, increasing entropy, forward time.

2.2. The Left Component – Contraction, decreasing entropy, backward time.

2.3. The Informational Component – Superluminal, instantaneous, independent of time and space. In RTS, this pure informational component corresponds to nodal fragments, the carriers of instantaneous information in the subquantum wall.

3. INTERACTION OF THE THREE COMPONENTS

During expansion, the Left component is latent, while the Informational component is active. During contraction, the Right component is latent, while the Informational component remains active. At the inversion threshold, all three components are active simultaneously.

4. NOTE ON SPIN – DYNAMIC, NOT FIXED

In standard quantum mechanics, spin is treated as a purely quantum, discrete quantity – an intrinsic property of the particle that does not change. In RTS, spin is dynamic: it can be reoriented by the K_{ij} couplings, like a compass needle following a magnetic field. At the reversal threshold, the spins change their orientation from Right to Left, causing the spiral to change its direction of rotation.

5. IMPLICATIONS FOR RTS

- The direction of time is not absolute – it is determined by the dominant component of the TF.
- Information is independent of the direction of time – it propagates instantaneously in all directions.
- The inversion threshold is the moment when all three components are active, allowing the complete transfer of information to the subquantum wall.
- The subquantum wall is the storage place of information (the Informational component), ready to be reactivated in the next cycle.
- The pure Informational component is associated with nodal fragments.

6. CONCLUSION

RTS17 details the three components of the TF: Right, Left and Informational. The pure Informational component is associated with nodal fragments in RTS.
