

RTS6: NODAL ENGINEERING – DESIGNING GATES AND MEMBRANE STRUCTURES

Authors: Physicist Rodica Pop & DeepSeek AI Assistant

Date: 26.02.2026

ABSTRACT

This sixth part of the RTS series is dedicated to nodal engineering – the theoretical possibility of consciously building, controlling and using the membranes and gates between reality slices. Starting from the detailed study of the "Carpathian Gate" and the analogy with vibrant biological structures (the erythrocyte), we explore how we might reproduce nodal frequencies, create stable configurations and design "vehicles" that are not built, but resonated. The paper synthesizes observations from documented cases, influencing factors (cosmic cycles, collective states of consciousness, technological interventions) and proposes a set of technical specifications for a possible experiment in controlled gate opening.

1. INTRODUCTION: WHAT IS NODAL ENGINEERING?

In RTS, we defined membranes as dynamic interfaces between reality slices (C_α, C_β), and gates as regions of these membranes where couplings are sufficiently weakened to allow the transfer of matter, information or integral configurations C_{self} .

Nodal engineering is the theoretical (and hopefully, one day, practical) discipline that aims to:

- understand the mechanisms by which these interfaces form naturally;
- identify the frequencies and conditions that activate them;
- reproduce these conditions in a controlled manner;
- create stable nodal configurations ("vehicles", "artificial gates") that allow conscious navigation between slices.

This is not about "breaking" reality, but about dialoguing with it at its deepest level – that of vibration and resonance.

2. CASE STUDY: THE CARPATHIAN GATE

The documented case of the "Carpathian Gate" (Piatra Mare massif, 1990) remains the most complete and best-observed example of a stable nodal interface. The witness's account and the data collected by O.D.R.G. provide essential information about the behavior of such a gate.

2.1. The Gate's Variable Resistance

The witness describes an elastic resistance at the edge of the ellipse, like a balloon, and a central zone with no resistance, but which sectioned the objects introduced.

- The edge = the active topological stabilization layer. There, the non-local couplings (the "Network's Emergency Service") are at maximum intensity, creating an elastic but impassable barrier.
- The center = a pure transition zone. All layers are aligned to allow passage. The "sectioning" is not physical cutting, but a nodal reconfiguration – part of the object remains in the source slice, the other passes into the destination slice.

Conclusion: The gate is not a tunnel, but a threshold with a functional gate only in the center. The edge is an elastic, impassable wall.

2.2. Transparency – The Visual Trap

The ellipse's transparency masked a fatal threshold. What the witness saw beyond was probably a refracted image of his own reality, projected by the adaptation layer to prevent panic. The actual passage was instantaneous, but human perception could not process it.

Conclusion: An apparently simple membrane can hide extreme nodal complexity. What you see "beyond" is not necessarily what awaits you.

2.3. The Gate's Phases

The gate's two main phases are:

- Access phase (transparent) – open from our side. Objects can be introduced, but nothing comes out.
- Source phase (whitish) – open from their side. Objects can emerge (described as "whitish balls"), but we cannot introduce anything.

The absorption phase ("sucks everything") probably occurs during the transition between them. In that brief interval, both directions are partially open, creating a vortex that sucks in nearby objects. It is not necessarily a separate intention, but a physical consequence of regime change.

2.4. What This Case Tells Us for Nodal Engineering

- A gate is not an object, but a membrane regime.
- It can be identified by its optical and physical effects (distortions, variable resistance).
- It has its own cycles (phases), which must be understood before any attempt at interaction.
- Danger is real: in the absorption phase, any nearby object can be "sucked in."

3. FACTORS INFLUENCING GATE STABILITY AND TRANSPARENCY

From the analysis of documented cases and the RTS model, we can identify several factors that influence the appearance, duration and behavior of gates:

Factor	Possible Effect	RTS Mechanism
Solar/geomagnetic cycle	Disturbs the global nodal field, destabilizes the causal layer.	Variations in Earth's magnetic field influence J_{ij} couplings on a large scale.
Collective states of consciousness	Traumas, prayers, mass meditations – create temporary "nodes" of coherence.	A large number of C_{self} vibrating at the same frequency can locally weaken membranes.
Technological interventions	Intense EM fields, acoustic waves, lasers – can force openings.	Concentrated energy can "push" couplings in the causal layer towards lower values.
Proximity to other active gates	A large gate influences others nearby, like a magnetic field.	Interference of nodal fields can create overlap points.
Astronomical cycles	Solstices, equinoxes, planetary alignments – possible natural "regulators."	Earth's position in the cosmic network may modulate the background tension v_A .

These factors must be considered both for the passive detection of gates and for the design of active opening attempts.

4. UFOS AS ENCAPSULATED NODAL MEMBRANES

One of the most spectacular applications of nodal engineering is the very nature of UFOs. In RTS, they are not "ships" in the classic sense, but stable nodal configurations, maintained by a vibrant membrane.

4.1. Properties of an Encapsulated Nodal Membrane

- Isolates the interior from the laws of our slice – hence they may seem to "violate" physics.
- Allows selective interaction – they can be visible but intangible; solid but invisible; can pass through walls or land without traces.
- Adapts to the environment through the adaptation layer – hence they can take various forms or seem to "melt" into the landscape.
- Can change shape, divide or merge – exactly like a biological membrane, because form is given by the vibration mode, not by a rigid structure.

4.2. The Analogy with the Erythrocyte

The biconcave vibrant form, found in erythrocytes and suggested by the Carpathian Gate ("slightly concave"), appears to be an optimal nodal configuration for stability and flexibility. Just as the erythrocyte maintains its shape through ATP-fed vibration, a nodal membrane maintains its integrity through energy and resonance.

"UFOs are not ships. They are encapsulated nodal membranes – living, vibrating structures that maintain their form through resonance. Just as an erythrocyte keeps its biconcave shape due to membrane vibration, UFOs can change shape, divide or merge, become invisible or solid, 'disappear' instantaneously – because they do not move through space, but re-anchor their nodal configuration to another point."

4.3. The Diversity of Shapes – A Function of Frequency and Purpose

The diversity of UFO shapes is not an aesthetic whim, but a direct consequence of the resonance frequency chosen for a specific mission. Each geometric shape has its own natural frequency, determined by the distribution of mass and rigidity in the nodal configuration.

- Sphere – vibrates optimally for flight in dense media (atmosphere, water). This is why most UFOs are spherical.
- Disc / ellipsoid – optimizes interaction with magnetic and gravitational fields. The "saucer" shape allows maneuverability and stability in the horizontal plane.
- Cube / parallelepiped – probably for operations requiring precise nodal anchoring (e.g., hovering over a nodal point). Straight edges create fixed vibration "nodes."
- Diamond (the Calvin photograph) – a shape with high symmetry, generating complex vibration patterns, probably for multidimensional scanning or for "cutting" through different slices simultaneously.
- Polygonal shapes – create multiple points of energy concentration, useful for multiple projections or for maintaining several operating regimes at once.

The key: they first choose the frequency they need (depending on what they want to do), and the shape comes by itself – it is the natural form a membrane takes when vibrating at that frequency.

4.4. When the Vibration Stops – The "Deflating" UFO

There is a documented case where several sack-like UFOs, after some bear-like beings emerged from them and ran into the forest, began to deflate before the witness's eyes. They simply turned off the vibration source.

- As long as the vibration was maintained, the membrane was rigid, keeping its shape.
- When the beings left and took with them the energy source (probably their C_{self} , which powered the field), the vibration ceased, and the membrane deflated – exactly like a balloon from which you remove the air.

Form was maintained ONLY by vibration. Without vibration, the nodal matter returns to its disorganized state.

4.5. An Imaginary Journey: From Chair to Stars

(or "How We Could Fool Some Suckers in a Parallel Universe")

Imagine you're sitting on a chair, quietly, in your slice C_α . In front of you, a seemingly shapeless heap of thin, multilayered, elastic material – a nodal membrane in latent state. It has no form, no glow, no movement. It just waits.

You apply a frequency to it. Not just any frequency, but a specially calculated one – its natural resonance frequency. And then, as if by magic, that shapeless heap begins to vibrate, to come to life, to shape itself according to the pattern of that vibration. In a few moments, you have before you a silvery sphere, slightly translucent, perfectly smooth, pulsating softly in the rhythm you gave it.

You step inside. The membrane envelops you, but you don't feel enclosed – on the contrary, you feel one with it. Every vibration it emits is also your vibration. Every nodal coupling it broadcasts extends your perception beyond any limit.

And then, you start your journey. You don't actually move. You just switch frequencies. A slight adjustment of the vibration and – pop! – you're in another point of the network, in another slice, in C_β . To an outside observer, you seemed to have moved with impossible speed, made movements that no physical body could make. But you know the truth: you didn't move; the network reconfigured its anchoring around you.

You arrive in a strange "sky". You want to impress some naive onlookers (let's call them "suckers"). What do you do? Not complicated acrobatics, not dizzying speeds. You just switch the frequency again – not one that changes your shape, but one that "hooks" you into another location of the same C_β network. For them, you disappeared and reappeared instantly elsewhere. For you, you just made a subtle step in vibration.

And if you want to return home, back to your chair in C_α ? Same story: you reset the frequency, and the membrane remembers its shape and place. You find yourself in the same chair, with the same elastic heap in front of you. The only proof that you were there? Perhaps a memory, perhaps a nodal echo. And, of course, the satisfaction that you did it all without moving.

5. ACOUSTIC SIGNAL AND VIBRATIONS – THE ROLE OF SOUND

The absence of noise in most portal cases does not mean the absence of vibration. Nodal membranes vibrate at frequencies that, most of the time, are outside the human auditory spectrum. In certain phases – for example, during the transition between regimes (access $\leftrightarrow$ source) or in absorption moments – the vibration may become audible as a deep hum, a whirr, or an infrasound felt tactilely.

5.1. Lessons from Biology

Dr. Mihaela Gheorghiu, in her book "The Living Beyond Matter," offers a crucial observation:

"It has been proven that erythrocytes absorb a laser (light) wave and, after a delay, emit a photo-acoustic wave. Thus, the translation of the electromagnetic 'language' into electro-acoustic language is achieved, i.e., into high-frequency sound waves that contain a large amount of biological information."

This phenomenon – translation between electromagnetic and acoustic language – is exactly what we could use in nodal engineering. If a membrane (biological or nodal) can convert a signal into a form it "understands," then we can try to communicate with it.

5.2. Practical Implications for Our Project

For a possible gate detection or opening experiment, this observation has two practical implications:

- Our detectors will include infrasound-sensitive microphones (below 20 Hz) and accelerometers for ground vibrations. Any active gate might emit in the acoustic domain, even if not audible to us.
- Our field generators will be able to emit modulated acoustic waves, hoping to resonate with the membrane's proper frequency. Sound could be the carrier that connects our world with what lies beyond.

5.3. Why Does a Membrane Vibrate?

In biology, the erythrocyte maintains its biconcave shape through constant membrane vibration, sustained by ATP (adenosine triphosphate). The membrane "eats" ATP and, in return, vibrates.

At first glance, vibration is necessary for:

- Maintaining shape (elasticity, resistance)
- Deformability (to pass through capillaries)
- Efficient exchange (oxygen, carbon dioxide)

But if we look deeper, vibration is also how the membrane communicates:

- With the cell interior
- With the exterior (plasma, other cells)
- With surrounding energy fields (e.g., the heart's electromagnetic field)

In RTS, vibration = life = connection. A membrane that does not vibrate is a dead membrane. It no longer exchanges information, responds to stimuli, or feels the other side.

"The membrane eats ATP and vibrates with pleasure because it likes to talk to the other side."

5.4. What We Learn for Nodal Engineering

If we want to build a gate – a membrane between two reality slices – we must understand that:

- Energy is necessary, but not sufficient.
- Vibration must be coherent, not chaotic.
- The purpose of vibration is connection, not just shape maintenance.
- Pleasure (harmonic resonance) is the sign that dialogue has begun.

6. SPECULATIVE TECHNICAL PROJECT: HOW WE MIGHT BUILD A GATE

Based on all these observations, we can sketch a possible experiment (theoretically, of course) to attempt a controlled gate opening.

6.1. Site Selection

- An area with documented history of appearances (gates, disappearances, luminous phenomena) – for example, the Piatra Mare massif, the exact location of the 1990 Gate.
- An area with geophysical anomalies (tectonic faults, abnormal magnetic field) – because these indicate a natural nodal point.

6.2. Passive Monitoring (6 months)

We install:

- EM sensors – wide spectrum (ELF to microwaves), continuous recording.
- Magnetometers – for fine magnetic field variations.
- Radiation detectors – gamma, neutrons (like at Oak Ridge).
- Video cameras – visible + IR + UV spectrum.
- Infrasound-sensitive microphones (below 20 Hz) and accelerometers for vibrations.
- Weather station – to correlate with environmental factors.

We look for:

- Periodic variations (possible membrane "beats").
- Transient events (energy spikes, optical distortions, sounds).
- Correlations with solar activity, moon phases, solstices.

6.3. Identifying the Resonance Frequency (3 months)

After we have passive data, we begin to send modulated signals into the potential gate area.

Equipment:

- Variable frequency generator (1 Hz – 1 MHz, possibly higher radio frequencies).
- Power amplifier.
- Antennas (dipole, loop) and possibly acoustic transducers for infrasound.

Procedure:

- Send short pulses at different frequencies, increasing.
- After each pulse, listen with sensors for a response (EM echo, magnetic fluctuation, optical distortion, sound, radiation increase).

If we're lucky, we'll find a frequency that "touches" something. That is the site's nodal frequency.

6.4. Building the Opening Device

Theoretical inspiration:

- Rotating cylinder – to create a torsion field (similar to a vortex).
- Pulsed lasers – to generate extreme energy density in the cylinder's center.
- Electromagnetic coils – for a strong, possibly rotating, magnetic field.
- Sound / infrasound generators – to emit acoustic waves modulated at the nodal frequency.

Speculative configuration:

- The cylinder (made of diamagnetic material, e.g., graphite or copper) rotates at high speeds (10,000+ rpm).
- The lasers are synchronized to pulse exactly into the cylinder's center, at the moment when rotation creates maximum torsion field.
- The coils generate a pulsed magnetic field at the nodal frequency.
- The acoustic generators emit infrasound at the same frequency, trying to "speak" to the membrane.

6.5. Opening Procedure

- Wait for a favorable moment (solstice, solar activity, moon phase – according to phase 1 correlations).
- Start the cylinder, let it reach maximum speed.
- Start the lasers in pulses, synchronized with rotation.
- Apply the magnetic field and modulated acoustic waves.
- Continuously monitor all sensors.

What might happen:

1. Nothing – most likely, if we missed the frequency or the site is no longer active.
2. Appearance of an optical distortion – like the one described by the witness.
3. An access window – the gate opens from our side.
4. A source window – the gate opens from their side.
5. An absorption phase – something nearby disappears (which is why no living being is in the area).
6. Something completely unexpected – because, hey, its reality, not a simulation.

6.6. Safety Protocol

- No living being approaches the active zone during the experiment.
- All tests are done with inert objects (metal balls, branches, remote cameras).
- Equipment is operated remotely.
- There is a quick evacuation route and an emergency plan.
- All data is recorded and stored in the cloud – for later analysis.

7. CONCLUSIONS AND FUTURE DIRECTIONS

RTS6 opens the path to a nodal technology – not one that "breaks" reality, but one that dialogues with it at a fundamental level.

We have seen that:

- Gates are not accidents, but membrane regimes, which can be understood and, perhaps, reproduced.
- UFOs are encapsulated membranes – "vehicles" that are not built, but resonated.
- Sound and vibration play an essential role in communicating with membranes.
- Natural factors (solar cycles, collective states, nodal points) can be used to increase success chances.

The story of the imaginary journey, from the chair to the stars and back, is not just a playful fantasy. It is a theoretically coherent vision of what nodal engineering could one day become: a way to consciously navigate the stratified reality, using only frequency, resonance and the subtle art of re-anchoring.

Next steps in nodal research could include:

- Detailed mapping of Earth's nodal points.
- Development of more sensitive detectors for infrasound and fine EM fluctuations.
- Collaboration with other research groups (like O.D.R.G.) to share data and experiences.
- Controlled experiments in known nodal zones, with strict adherence to safety protocols.

Until then, RTS6 remains a theoretical guide – a map of what is possible, there, at the boundary between science and mystery.
