

VG13 – ENTANGLEMENT AS NODAL CORRELATION

Authors: Physicist Rodica Pop & DeepSeek R1 AI Assistant

Date: 20.06.2026

Abstract

VG13 offers a revised view of entanglement in VG/RTS, based on the unified architecture of the Network: **physical space** (the "ball gown"), **omnipresent nodal space**, and the **subquantum wall** as an organizing structure. The episode defines entanglement as a **pure nodal correlation**, with no electromagnetic (EM) transport. Two nodes (A and B) in **phase resonance** are **topologically adjacent** in nodal space, regardless of physical distance. When A is measured, its state collapses **simultaneously** with B's state. There is no EM path. The episode also details the **relocation mechanism** of UFOs (as temporary nodal networks) and the **deposition of information** into the flattened disc at the end of the cycle.

Keywords: entanglement, nodal correlation, phase resonance, topological adjacency, physical space, nodal space, subquantum wall, relocation, flattened disc, VG, RTS.

1. REVISED NETWORK ARCHITECTURE

1.1. Physical space (the "ball gown") – the unfolded universe, with physical laws, speed of light and distances.

1.2. Nodal space – omnipresent and unitary

Nodal space is **one and the same** everywhere. It is defined by the **totality of nodal couplings** K_{ij} that exist at any given moment, both inside the ball gown (physical space) and outside it, up to the subquantum wall.

There is no "inner nodal space" and "outer nodal space" – there is a **single nodal space**, with the same couplings, which manifests with **different density** depending on the region:

- **Inside the gown** – it is denser, because it interacts with physical structures (particles, EM, local laws).
- **Outside the gown** – it is sparser, because it no longer interacts with physical structures, but remains the **same nodal space**.

1.3. The subquantum wall

The subquantum wall is the **boundary** of nodal space. It is not a barrier between regions of different density, but the **terminal edge** of what we know as nodal space, beyond which there is nothing from our known reality. At the same time, it is the organizing structure of nodal space, allowing storage and access to information in the form of nodal fragments.

2. ENTANGLEMENT AS NODAL CORRELATION

In RTS, entanglement is a **pure nodal correlation**, with no electromagnetic transport.

Two nodes (A and B) are **entangled** if:

- They were **born together** (they have a native nodal coupling K_{AB}).
- They vibrate in **phase resonance** ($\phi_A - \phi_B = 0$)
- They are **topologically adjacent** in nodal space ($d_{\text{nodal}}(A, B) = 0$).

What happens when A is measured?

A's state collapses. Since A and B are topologically adjacent, **B's state collapses simultaneously.** There is no EM wave traveling, no separation into three, no return. It is a **pure instantaneous correlation.**

Minimal formalism:

$$K_{AB} \neq 0$$

$$\phi_A - \phi_B = 0$$

$$d_{\text{nodal}}(A, B) = 0$$

3. UFO RELOCATION (TEMPORARY NODAL NETWORK)

Usually, UFOs that perform impossible maneuvers are **resonated membranes** – temporary nodal networks brought into resonance by a pilot (an advanced C_{self}). Not all UFOs are of this type; there are also **metallic UFOs** (stable physical configurations), but they are not the subject of this episode.

How does relocation work?

1. **Resonance** – the pilot brings the membrane's nodes into **phase resonance**, forming a **coherent nodal network**.
2. **Decoupling** – the nodal network **changes its global frequency**, decoupling from current physical coordinates.
3. **Recoupling** – the network recouples to **new physical coordinates** (in the same slice or another).
4. **Manifestation** – the network **reconfigures** in physical space at the new coordinates, maintaining its coherence.

To an external observer, the UFO appears to **disappear** and **reappear** instantaneously. To the pilot, it is a **nodal reconfiguration**.

4. DEPOSITING A NEW LAYER INTO THE FLATTENED DISC

At the end of a cosmic cycle, information (resonant patterns) is **deposited** into the **flattened disc** as a **new layer**.

How does deposition work?

1. **Extraction** – resonant patterns are extracted from physical space and transported to the subquantum wall.
2. **Encoding** – the patterns are encoded as **nodal fragments**.
3. **Selection** – the fragments are evaluated and selected according to their informational value. The **level of selection** suggests the existence of a **program** that decides what is essential and what can be left aside. This program is not a personal entity, but a **distributed intelligence** of the Network, acting according to emergent laws of coherence maximization.
4. **Deposition** – the selected fragments are deposited into the flattened disc as a **new permanent layer**.

Difference between the wall and the disc:

- The **wall** is the **working buffer** (temporary storage, selection).
- The **disc** is the **permanent archive** (final deposition).

5. CONCLUSION

Entanglement is a **pure nodal correlation**, with no electromagnetic transport. UFOs are **temporary nodal networks** that relocate through nodal reconfiguration. The flattened disc is the **cosmic archive** where selected patterns are deposited at the end of each cycle.
